# 1. Terms

1. EQcoin is the original commodity of EQcoin ecosystem. EQcoin is a cryptocurrency, hereinafter referred to as "**EQC**".
2. "**ID**" is an abbreviation for "identity".
3. Type represents the type of lock, hereinafter referred to as "**T**".
4. Operation is defined in [Section 2.7.1](#) below, hereinafter referred to as "**OP**".
5. Elliptical curve cryptography, hereinafter referred to as "**ECC**".
6. "**nonce**" is an abbreviation for "number used only once".
7. Transactions per second, hereinafter referred to as "**TPS**".
8. Proof of Stake, hereinafter referred to as "**PoS**".
9. Proof of Work, hereinafter referred to as "**PoW**".

## **2. EQcoin Overview**

### **2.1 About EQcoin**

EQcoin is the world's first Passport-based decentralized finance ecosystem of the people, by the people, for the people. EQcoin is an open-source, decentralized, permissionless, distributed, and publicly shared digital ledger. Passport and EQC (an abbreviation for "EQcoin") are the original commodities of the EQcoin ecosystem. Passport and EQC are issued and circulated in accordance with the EQcoin consensus mechanism, which operates on decentralized finance principles. This enables everyone to participate in the issuance and circulation of Passport and EQC through crowdsourcing. The development of EQcoin is based on crowdsourcing. Everyone can contribute to the enhancement and refinement of EQcoin through the EQcoin Improvement Proposal (EIP).

#### **2.1.1 Features of EQcoin**

##### **2.1.1.1 Passport-based blockchain module**

EQcoin invented the first Passport-based blockchain model.

It enables users to easily manage and trade digital assets, improving their efficiency, trust, comfort, satisfaction, and loyalty by reducing complexity and providing an intuitive, user-friendly experience similar to iPhone.

#### **2.1.1.1 Blockchain Model Comparison of Bitcoin, Ethereum, and EQcoin**

#### **2.1.1.2 Supports performing multiple different operations in the same transaction**

Users can perform multiple operations such as Transfer, SmartContract, IssuePassport, ChangeLock, and multiple OPs

at the same time in the same transaction, thus saving transaction fees and providing a better user experience.

#### **2.1.1.3 User-based issuance and sale of Passports and deployment of smart contract services.**

Passport owners can provide services for issuing and selling passports, as well as deploying smart contracts for all users.

#### **2.1.1.4 A currency supply model with a constant total supply and is much more scarce than Ethereum**

EQcoin effectively combats inflation by implementing a currency supply model with a constant total supply, similar to Bitcoin. The decimal of EQcoin is 8, and its circulation and annual issuance are lower than those of Ethereum, which makes it more scarce and more resistant to inflation than Ethereum.

##### **2.1.1.4.1 EQcoin and Ethereum currency supply comparison**

Compare items	EQcoin	Ethereum
Genesis block supply	21,000,000~70,000,000 ETH	72,000,000 EQC
Annual supply	6,307,200 EQC	About 6,400,000

		ETH
Decimal	8	18
Constant total supply	Yes	No

Note1: Ethereum currency supply data comes from [Conducting the ETH Census - by Kyle Waters \(substack.com\)](https://substack.com/p/kyle-waters/conducting-the-eth-census).

Note2: According to the above data sources, the current total issuance of Ethereum is about  $1.2 \times 10^8$  ETH =  $1.2 \times 10^{28}$  wei. The maximum supply of EQcoin is  $2.1 \times 10^{11}$  EQC =  $2.1 \times 10^{19}$  singularity. Comparing their smallest denomination, the current total issuance of Ethereum is approximately  $(1.2 \times 10^{28}) / (2.1 \times 10^{19}) = 571,428,571$  times the maximum supply of EQcoin. So EQcoin is a much more scarce resource than Ethereum.

#### **2.1.1.5 Support the deployment and operation of more cost-effective smart contracts compatible with Ethereum**

EQcoin supports the deployment and execution of more cost-effective smart contracts that are compatible with Ethereum, establishing a decentralized finance ecosystem that is more cost-effective than Ethereum.

#### **2.1.1.6 High TPS and low transaction fees**

EQcoin achieves a high Transactions Per Second (TPS) comparable to EOS and low transaction fees comparable to Polygon. This provides users with a faster and more cost-effective transaction experience compared to Ethereum.

#### **2.1.1.7 Flexibility to combine and extend protocols and state objects**

EQcoin enables the flexibility to combine and extend protocols and state objects, facilitating adaptation to evolving requirements by modifying protocol and state object statuses. Additionally, it can meet new demands by extending protocols and state objects.

#### **2.1.1.8 Minimization of state data**

EQcoin significantly reduces the cost of operating a full node by implementing state data minimization. This enables more users to afford the operational costs and ensures the decentralization of EQcoin.

### **2.1.1.9 Consistency in transaction sorting and execution order**

EQcoin ensures consistency in transaction sorting and execution order, effectively preventing fraud and meeting the relevant requirements of decentralized applications (DApps), such as decentralized exchanges (DEX) or auctions.

## **2.2 About Passport**

Passport is the cornerstone of the EQcoin ecosystem. Passport is user-controlled and can be used for depositing digital assets, sending transactions, and deploying an independent smart contract. A Passport has a Status, an ID, a Balance, a Nonce, a Lock, a Key, and a SmartContract. Passport owners can provide services for issuing and selling passports, as well as deploying smart contracts for all users. They have the authority to determine the amount of EQC to be charged for passport issuance, sales, and deployment of smart contracts. Just like a Bitcoin address and an Ethereum account, a Passport is anonymous and does not contain personal information about the owner.

## **2.2.1 PoS based Passport issuance consensus mechanism**

In order to issue a new Passport, a specific amount of EQC must be staked in it.

### **2.2.1.1 List of the amount of EQC that needs to be staked for different Passports**

Passport ID No.	The amount of EQC that needs to be staked
0~9	51
10~99	51
100~999	51
1000~9999	51
10000~99999	51
100000~999999	51
1000000~9999999	51
10000000~99999999	25.5
100000000~999999999	12.75

### **2.2.2 About Status**

Status uses the bit flags to record the current

Passport-related status, such as whether there is a smart contract deployed, staking mode, whether it is active, etc.

The type of Status is [EQCBits](#). Using the Status, Passport can add or delete Passport relevant state objects created by the EQcoin Improvement Proposal to add or delete its specific functions.

### **2.2.3 About ID**

Each Passport is assigned a unique identifier when it is issued, which is its ID. Passport can be referenced using its ID. It is a natural number. The numbering starts from 1 and increases sequentially based on the order of Passport issuance.

### **2.2.4 About Balance**

Balance stores the balance of the Passport in Singularity.

### **2.2.5 About Nonce**

Nonce of a Passport records the total number of transactions that have been sent and confirmed by this Passport using a specific Lock. Nonce ensures that the transaction signed by the Lock bound to the current Passport

is unique to the current Lock, thereby avoiding double-spending attacks.

The value starts at 0 and increases by 1 with each sent and confirmed transaction, and is reset to 0 after each Passport Lock change.

### **2.2.5 About LockNonce**

LockNonce of a Passport records the total number of times the current Passport has changed its Lock. LockNonce itself is not a component of the transaction. When signing and verifying transactions, LockNonce will be superimposed as dependency-injected data behind the original data of the transaction and treated as a whole for signing and verification.

The value starts at 0 and increases by 1 after each Passport lock change.

### **2.2.6 About Lock**

Lock is used to safeguard and control the ownership of the Passport, ensuring that only its owner can use it to send transactions, thus preventing it from being illegally stolen by others. Locks are implemented based on various encryption technologies such as Elliptical curve cryptography (ECC) and

SHA-3. Lock has a Type, Body and possibly other relevant state objects. Lock consists of two lock types at the current stage. New locks can be created through EQcoin Improvement Proposal to extend the functionality of the lock.

#### **2.2.6.1 About Type**

Type represents the type of Lock. The type of Type is [EQCBits](#).

#### **2.2.6.2 About Body**

Lock body is implemented based on various encryption technologies. It is the main part of the lock. Different types of locks may have different lock body implementation methods.

#### **2.2.6.3 Elliptical curve cryptography (ECC) based Lock**

Elliptical curve cryptography (ECC) based Lock use ECC technology to safeguard and control the ownership of relevant Passports.

##### **2.2.6.3.1 T0 lock**

T0 lock's lock type is 0 and use secp256r1(NIST P-256) elliptic curve to safeguard and control the ownership of relevant Passports. T0 lock has a lock type 0, a SHA3-256

public key hash of secp256r1(NIST P-256) elliptic curve. It has self-check-based error correction capabilities that can detect its character errors caused by reading, input or network transmission, thereby ensuring its correctness.

#### **2.2.6.3.2 T1 lock**

T1 lock's lock type is 1. It can provides multi-party safeguard and control the ownership of relevant Passport and 0-trust-based Passport security control services against loss and damage of private keys. T1 lock has a LockType, a Status, a SHA3-256 hash of the relevant redundant lock pairs. It has self-check-based error correction capabilities that can detect its character errors caused by reading, input or network transmission, thereby ensuring its correctness.

The T1 lock supports the following functions:

1. User is allowed to create a redundant lock pair, which contains  $N$  ( $1 \leq N \leq 4$ ) T0 locks from different devices provided by the user. User can select a lock to unlock from the redundant lock pair. Thus, if a single device is damaged, the locks in the redundant devices are still available for use.
2. Single user is allowed to create  $N$  ( $1 \leq N \leq 8$ ) lock pairs, and

select the  $M(1 \leq M \leq N)$  locks in the  $N$  lock pairs to unlock.

3.  $N(1 \leq N \leq 8)$  users are allowed to provide one lock pair per user and must use the  $N$  locks in the  $N$  lock pairs to unlock.

## **2.2.6 About PublicKey**

PublicKey has a Status, one or more public keys that used to verify Passport relevant digital signatures. Because the corresponding public keys is stored in relevant Passport when the lock is unlocked for the first time, so that it can resist preimage attacks.

## **2.2.7 SmartContract**

### **2.2.7.1 About smart contracts**

Smart contracts are similar to the contracts and agreements in the real world. The only distinction is that they are digital. In fact, a SmartContract is a specialized type of computer program designed to execute, control, or document events and actions in accordance with the terms of a contract or an agreement. It has a Status, an Identity, a Balance, a Nonce, a CodeHash and a StateRoot. It runs on EQCVM, itself and its related state object data are stored on the EQcoin blockchain. Once this data is recorded, it becomes traceable and

irreversible.

Smart contracts are written in Intelligent. Smart contracts enable trusted transactions, contracts, and agreements to be conducted among diverse, anonymous parties without requiring a central authority, legal system, or external enforcement mechanism.

Smart contract is deployed in Passport. Each Passport can deploy an independent smart contract and it has the same ID as the Passport. Smart contract can be referenced using its ID.

#### **2.2.7.2 About SmartContract**

SmartContract stores the state objects related to the smart contract currently deployed in Passport.

##### **2.2.7.2.1 About Status**

Status uses the bit flags to record the current SmartContract-related status.

The type of Status is [EQCBits](#). Using the Status, SmartContract can add or delete SmartContract relevant state objects created by the EQcoin Improvement Proposal to add or delete its specific functions.

#### **2.2.7.2.2 About Balance**

Balance stores the balance of the SmartContract in Singularity.

#### **2.2.7.2.3 About Nonce**

Nonce of a SmartContract records the total number of transactions that have been sent and confirmed by this SmartContract. The value starts at 0 and increases by 1 with each sent and confirmed transaction.

#### **2.2.7.2.4 About CodeHash**

CodeHash stores the hash of the smart contract code.

#### **2.2.7.2.5 About StateRoot**

StateRoot stores the state objects' MerklePatriciaTrie root of the smart contract currently deployed in Passport.

### **2.3 About EQC**

EQC is an abbreviation for "EQcoin". It is the original commodity of EQcoin ecosystem. It is a cryptocurrency. Users need to pay EQC to use EQcoin decentralized financial services.

### **2.3.1 About Singularity**

Singularity is the smallest denomination of EQC. One EQC = 100,000,000 singularity ( $10^8$ ).

### **2.4 Passport and EQC total supply**

The max total supply of Passport is 4,294,967,296.

The total supply of EQC is a constant 210,000,000,000 and the decimal is 8. The first block, the Singularity block, will issue at least 21,000,000 EQCs but no more than 70,000,000 EQCs, and then will issue 6,307,200 EQCs every year.

### **2.5 About Intelligent**

Intelligent is an object-oriented programming language designed for developing smart contracts that run on EQcoinVM. It is compatible with Solidity. It is statically typed, supports inheritance, an Intelligent Standard Library, and complex user-defined programming.

#### **2.5.1 About Intelligent Standard Library (ISL)**

The Intelligent Standard Library (ISL) provides a wide range of features that significantly expand the core Intelligent language, enhancing its versatility. The ISL is a collection of

algorithms, data structures, and other components that can be used to simplify the development of Intelligent programs. The ISL is a collection of Intelligent contracts and interfaces designed to provide commonly used programming data structures and functions, such as tokens, utilities, access control, upgrades, etc. One of the primary advantages of ISL is that it provides the ability to import specific versions of contracts and interfaces included in ISL through an import statement, so there is no need to include ISL-related source code when deploying smart contracts. This can significantly reduce the cost of deploying smart contracts.

## **2.6 About EQcoin virtual machine(EQcoinVM)**

EQcoin virtual machine(EQcoinVM) is a crucial component of the EQcoin blockchain. It serves as the runtime environment for managing the state of state variables , enabling smart contract functionality, executing smart contracts and decentralized applications (DApps). It operates as a decentralized computer that runs on the global network of EQcoin nodes. It is responsible for processing and executing code written in EQcoin's native programming language, Intelligent. It is a Turing-complete, sandboxed execution

environment. It is compatible with the Ethereum Virtual Machine.

## **2.7 About EQswap**

EQswap is a decentralized exchange that uses an order book system to facilitate the trading of digital assets on the EQcoin blockchain. As a decentralized exchange, EQswap is permissionless, allowing everyone to trade digital assets or create a new market for exchanging a new pair of digital assets.

## **2.8 About Transaction**

Transaction is essentially a signed set of instructions from one Passport. Transaction is used to affect a state change on the EQcoin blockchain, such as transfer of digital assets, change the lock of Passport, deploy smart contract, or execute a function within a smart contract.

Transaction has a Status, a Passport ID, a Nonce , one or more body arrays, and a Signature. Using the Status, Transaction can add or delete bodies created by the EQcoin Improvement Proposal to add or delete its specific functions.

## **2.8.1 About Transaction Nonce**

Transaction Nonce is a number that is used only once in a specific transaction. EQcoin network stipulates that the nonce of a new transaction must be the current Nonce of its Passport plus one. Therefore, each new Transaction Nonce must be set to the current Nonce of its Passport plus one.

Transaction Nonce enables preventing replay attacks, which involve a malicious user trying to resend a previous transaction. It ensures that each transaction can be uniquely identified, ordered correctly, processed and verified accurately within the EQcoin blockchain.

## **2.8.2 About Operation**

Operation is essentially a set of instructions from one Passport. Operation is used to affect a state change on the EQcoin blockchain, such as change Passport's lock or deploy a smart contract. Each OperationBody contains one or more operations.

Operation has an OP ID and one or more OP state objects. New operations can be created through EQcoin Improvement Proposal to extend the functionality of the operation.

Operation consists of 2 operation types at the current stage:

## 1. ChangeLockOP

ChangeLockOP is used to change relevant Passport's lock.

ChangeLockOP has an OP ID of 0 and a lock which is the new lock for the current Passport.

## 2. ReservedNonceOP

ReservedNonceOP is used to reserve some nonces for future transactions, so that these reserved nonces can be used to execute some offchain transactions (such as EQC lightning network transactions), and these reserved nonces can be used to execute transactions update the relevant global state on the EQC network when needed.

ReservedNonceOP has an OP ID of 1 and a reserved nonce quantity(Values range from 1 to 256), which is the number of nonces reserved.

When the ReservedNonceOP is executed, the following operations will be performed:

1. The nonce of the current Passport will increase the number of reserved nonces.
2. The reserved nonce flag will be marked in the corresponding Passport's status state object (if necessary), and the value of the total number of reserved nonce state object will be increased according to the total number of

reserved nonces, and the corresponding reserved nonces' value will be added to the reserved nonce ZeroOneDynamicMerklePatriciaTrie.

Transaction consists of four body types at the current stage:

#### 1. IssuePassportBody

IssuePassportBody is used to issue passports. A maximum of 129 IssuePassportBodies can be included in the IssuePassportBody array.

#### 2. OperationBody

OperationBody is used to execute operation, for example ChangeLockOP. A maximum of 65 OperationBodies can be included in the OperationBody array.

#### 3. TransferBody

TransferBody is used to transfer EQC. A maximum of 257 TransferBodies can be included in the TransferBody array.

#### 4. SmartContractBody

SmartContractBody is used to execute smart contract function. A maximum of 5 SmartContractBodies can be included in the SmartContractBody array.

## 2.8.3 Transaction storage structure

The transaction storage structure consists of two state objects: L(length) state object(the transaction length, its data type is EQCBits, its count index does not start from 0 but from 69 (because the size of the smallest transaction is 69 bytes)) and V(value) state object(the transaction body).

## 2.9 Transaction use case

### 2.9.1 Issue Passport

1. Adam issues passport and transfers 101 EQCs for Eve (Lock: 0bb...bb).

Before Adam sends the transaction:

Adam's Passport
Status: 0
ID: 1
Nonce: 0
Balance: 2100000000000000
Lock: 0aa...aa
PublicKey: null

Transaction sent by Adam to issue Passport:

Transaction
-------------

<u>Status</u> <sup>1</sup> : 0000000 <u>1</u> <sup>2</sup>	
Passport ID: 1	
Nonce: 1	
IssuePassportBody	<u>Status</u> <sup>3</sup> : <u>0000000</u> <sup>4</sup> <u>0</u> <sup>5</sup>
	Lock: <u>bb...bb</u> <sup>6</sup>
	Value: 10100000000
Signature: xx...xx	

**The size of the transaction is 105 bytes.**

After Adam sends the transaction:

Adam's Passport
Status: 0
ID: 1
Nonce: 1
Balance: 2099989800090000

<sup>1</sup> The type of the Status state object is [EQCBits](#).

<sup>2</sup> Indicates whether transaction includes IssuePassportBody, 0: excludes, 1: includes.

<sup>3</sup> The type of the Status state object is [EQCBits](#).

<sup>4</sup> This state object includes a series of consecutive bits. When IssuePassportBody includes only one sub-IssuePassportBody uses it to record the lock type part of the current sub-IssuePassportBody's lock, and when IssuePassportBody includes multiple sub-IssuePassportBodys uses it to record the number of sub-IssuePassportBodys. The current record value is the lock type part 0000000(0) of the sub-IssuePassportBody's lock.

<sup>5</sup> Indicates whether IssuePassportBody includes multiple sub-IssuePassportBodys, 0: one, 1: multiple.

<sup>6</sup> When IssuePassportBody includes only one sub-IssuePassportBody uses it to record the hash part of the lock, and when IssuePassportBody includes multiple sub-IssuePassportBodys uses it to record the full lock. The current record value is the public key hash part bb...bb of sub-IssuePassportBody's T0 lock.

Lock: 0aa...aa
PublicKey: xx...xx

Eve's Passport
Status: 0
ID: 2
Nonce: 0
Balance: 10100000000
Lock: 0bb...bb
PublicKey: null

2. Adam issues passports and transfers 101 EQCs for Moses (Lock: 0cc...cc) and Noah (Lock: 0dd...dd) and charge the service fee of 1 EQC per person. Therefore, after deducting the service fee, the transfer amount is 100 EQC.

Before Adam sends the transaction:

Adam's Passport
Status: 0
ID: 1
Nonce: 1
Balance: 2099989800090000
Lock: 0aa...aa
PublicKey: xx...xx

Transaction sent by Adam to issue Passports:

Transaction	
Status: 00000001	
Passport ID: 1	
Nonce: 2	
IssuePassportBody	Status: <u>0000000</u> <sup>7</sup> <u>1</u> <sup>8</sup>
	Lock: 0cc...cc
	Value: 100000000000
	Lock: 0dd...dd
	Value: 100000000000
Signature: xx...xx	

**The size of the transaction is 144 bytes.**

After Adam sends the transaction:

Adam's Passport
Status: 0
ID: 1
Nonce: 2
Balance: 2099969800080000
Lock: 0aa...aa
PublicKey: xx...xx

---

<sup>7</sup> Indicates IssuePassportBody includes multiple sub-IssuePassportBodys.

<sup>8</sup> Record the current number of sub-IssuePassportBodys is 0000000(2).

Moses' Passport
Status: 0
ID: 3
Nonce: 0
Balance: 100000000000
Lock: 0cc...cc
PublicKey: null

Noah's Passport
Status: 0
ID: 4
Nonce: 0
Balance: 100000000000
Lock: 0dd...dd
PublicKey: null

## 2.9.2 Transfer

1. Adam transfers 101 EQCs to Moses.

Before Adam sends the transaction:

Adam's Passport
Status: 0

ID: 1
Nonce: 2
Balance: 2099969800080000
Lock: 0aa...aa
PublicKey: xx...xx

Transaction sent by Adam to transfer:

Transaction	
Status: 000 <u>0</u> <sup>9</sup> <u>1</u> <sup>10</sup> 000	
Passport ID: 0	
Nonce: 3	
TransferBody <sup>11</sup>	Passport ID: 2
	<u>Value</u> <sup>12</sup> : 10100000000
Signature: xx...xx	

**The size of the transaction is 72 bytes.**

<sup>9</sup> When transaction includes TransferBody indicates whether TransferBody includes multiple sub-TransferBodys, 0: one, 1: multiple, otherwise indicates whether transaction includes SmartContractBody, 0: excludes, 1: includes.

<sup>10</sup> Indicates whether transaction includes TransferBody, 0: excludes, 1: includes.

<sup>11</sup> EQcoin uses [EQCHelix](#) to store the transfer value and relevant Passport ID's bytes' length in TransferBody. On the underlying storage, Value is stored first, followed by Passport ID.

<sup>12</sup> The lowest 5 bits of the binary digits of Value are reserved as identifier bits to store the number of bytes occupied by Value and Passport ID respectively, among which the upper 3 bits are used to store the number of bytes occupied by Value and the lower 2 bits are used to store the number of bytes occupied by Passport ID. In the TransferBody, Value is stored first and then Passport ID is stored. Therefore, if the value of the transfer amount entered in TransferBody is not divisible by 32, some adjustments need to be made to make it divisible by 32 so that the lowest 5 bits of its binary digits are reserved as identifier bits. It is recommended to adjust it in the following ways: 1. Use the result of value-(value%32) as the transfer amount. 2. Use the result of value+(32-(value%32)) as the transfer amount.

## 2.10 About MerklePatriciaTrie

### 2.10.1 About ZeroOneMerklePatriciaTrie and ZeroOneDynamicMerklePatriciaTrie

ZeroOneMerklePatriciaTrie is used to store the Global State of the IDKey storage object(for example Passport 、 Transaction 、 active Smart Contract relevant state objects) in each block of EQcoin. The IDKey state object has a unique ID, which is a natural number encoded consecutively from zero. In the ZeroOneMerklePatriciaTrie, it is bit by bit addressed from high bit to low bit according to the binary value of the ID of

the relevant IDKey state object. ZeroOneMerklePatriciaTrie includes two types of keys, ZeroKey(0) and OneKey(1), they consist of only one bit(0 or 1).

Note : Due to the ZeroKey and OneKey contain only one character, there is no need to store it, and it can be obtained directly according to the corresponding status bit of its parent node.

ZeroOneDynamicMerklePatriciaTrie is used to store the Global State of the IDKey state objects(for example active and inactive Smart Contract relevant state objects) in each block of EQcoin. In the ZeroOneDynamicMerklePatriciaTrie, it is bit by bit addressed from high bit to low bit according to the binary value of the Hash of the relevant state object. ZeroOneDynamicMerklePatriciaTrie includes two types of keys, ZeroDynamicKey(0xxx) and OneDynamicKey(1xxx), they are consecutive binary sequences consisting of one or more bits starting with 0 and 1.

Note : When the ZeroDynamicKey and OneDynamicKey contain only one character, there is no need to store it, and it can be obtained directly according to the corresponding status bit of its parent node. When the ZeroDynamicKey and OneDynamicKey contain multiple characters, there is no need

to store its first character because it can be obtained directly according to the corresponding status bit of its parent node.

#### **2.10.1.1 About BinaryNode**

BinaryNode is the key node that constitutes the ZeroOneMerklePatriciaTrie or ZeroOneDynamicMerklePatriciaTrie dictionary tree. BinaryNode has a status, a key, a ZeroNode, a OneNode and a value. ZeroOneMerklePatriciaTrie includes only two BinaryNodes, ZeroNode and OneNode. BinaryNode's underlying storage implementation includes a HashKey(Hash of BinaryNode's binary raw data, used to support state object verification based on light client protocol) and a StorageKey(UpdateNonce(A natural number starting from 0 and increments by 1 with each modification of the BinaryNode) of BinaryNode, used to access state objects from StateDB).

#### **2.10.1.2 About BinaryNode Status**

BinaryNode Status is used to identify the composition of the state objects included in the BinaryNode. The type of the BinaryNode Status state object is [EQCBits](#). The default order of state objects that BinaryNode includes is: ZeroNode, OneNode, and Value.

BinaryNode Status consists of two status types at the current stage(in the underlying storage, they are compositely stored together):

1. HashStatus, the default universal identifier bit of the BinaryNode which participate in the calculation of the BinaryNode Hash.

000000<sup>33</sup>0<sup>34</sup>0<sup>35</sup>

2. StorageStatus, includes HashStatus identifier bit and storage relvant identifier bit of the BinaryNode which does not participate in the calculation of the BinaryNode Hash but it is used to get BinaryNode from StateDB.

2.1 When BinaryNode includes two state objects(ZeroNode&Value or OneNode&Value).

0000<sup>36</sup>0<sup>37</sup>000<sup>38</sup>

Note: The state object has the smallest StorageKey hereinafter referred to as "A" (when there are multiple equal value minimums, the one with the lowest default order is taken), another state object hereinafter referred to as "B" . If A's StorageKey equals B's StorageKey, the underlying data is A's StorageKey . If A's StorageKey is not equal to B's StorageKey,

---

<sup>33</sup> Indicates whether node includes OneNode, 0: excludes, 1: includes.

<sup>34</sup> Indicates whether node includes ZeroNode, 0: excludes, 1: includes.

<sup>35</sup> Indicates whether node includes Value, 0: excludes, 1: includes.

<sup>36</sup> Identifies whether the two state objects'storageKey are equal, 0: no, 1: yes.

<sup>37</sup> Identifies which node state object'storageKey is the smallest in the default order, 0: left, 1: right.

<sup>38</sup> These 3 identifier bits are the same as in HashStatus.

the underlying data is A's StorageKey and (B's StorageKey - A's StorageKey)(this saves more storage space than directly stores the two state objects'storageKey). For example, if B's StorageKey is 100,001 and the A's StorageKey is 100000, the underlying stored data is 100,000 and 1(this saves a lot of storage space than direct storage 100,000 and 100,001). When need to restore the B's StorageKey, can obtain its value through  $100000+1$ .

2.2 When BinaryNode includes three state objects(ZeroNode, OneNode and Value).

0<sup>39</sup>0<sup>40</sup>0<sup>41</sup>00<sup>42</sup>000<sup>43</sup>

Note: The state object has the smallest StorageKey hereinafter referred to as "A" (when there are multiple equal minimum values, the one with the lowest default order is taken), the state object after A in the default order hereinafter referred to as "B" (If A is Value, the order is calculated from the beginning, so B is ZeroNode) , the state object after B in the default order hereinafter referred to as "C" (If B is Value, the order is calculated from the beginning, so C is ZeroNode) . The one with the smaller StorageKey in B and C hereinafter referred to as "D" (when the StorageKey of B and C are equal, the one with the lowest default order is taken)and the The one with the

---

<sup>39</sup> Identifies whether E's StorageKey is equal to D's StorageKey, 0: no, 1: yes.

<sup>40</sup> Identifies whether D's StorageKey is equal to A's StorageKey, 0: no, 1: yes.

<sup>41</sup> Indicates B's and C's StorageKey who is bigger, 0:  $B \leq C$ , 1:  $B > C$ .

<sup>42</sup> Indicates which state object has the smallest UpdateNonce, 0: ZeroNode, 1: OneNode, 2: Value.

<sup>43</sup> These 3 identifier bits are the same as in HashStatus.

larger StorageKey in B and C hereinafter referred to as “E” (when the StorageKey of B and C are equal, the one with the highest default order is taken).

### 2.10.1.3 About ZeroNode

As shown in the figure below, the key of ZeroNode is 0.

### 2.10.1.4 About OneNode

As shown in the figure below, the key of OneNode is 1.

## 2.10.2 About HexMerklePatriciaTrie

HexMerkleDynamicPatriciaTrie is used to store the Global

State of the HashKey state object(for example Smart Contract relevant state objects) in each block of EQcoin. In the HexMerklePatriciaTrie, it is bit by bit addressed from high bit to low bit according to the binary value of the Hash of the relevant state object. HexMerklePatriciaTrie includes 16 keys, DynamicKey0(0xxx), DynamicKey1(1xxx), DynamicKey2(2xxx), DynamicKey3(3xxx), DynamicKey4(4xxx), DynamicKey5(5xxx), DynamicKey6(6xxx), DynamicKey7(7xxx), DynamicKey8(8xxx), DynamicKey9(9xxx), DynamicKeyA(Axxx), DynamicKeyB(Bxxx), DynamicKeyC(Cxxx), DynamicKeyD(Dxxx), DynamicKeyE(Exxx), DynamicKeyF(Fxxx), they are continuous hexadecimal string keywords starting from 0 to F respectively.

#### **2.10.2.1 About BranchNode**

BranchNode is the key node that constitutes the HexMerkleDynamicPatriciaTrie dictionary tree. BranchNode has a status, a key, a BranchNode0, a BranchNode1, a BranchNode2, a BranchNode3, a BranchNode4, a BranchNode5, a BranchNode6, a BranchNode7, a BranchNode8, a BranchNode9, a BranchNodeA, a BranchNodeB, a BranchNodeC, a BranchNodeD, a BranchNodeE, a BranchNodeF, and a Leaf.

HexMerkleDynamicPatriciaTrie includes 16 BranchNodes, BranchNode0, BranchNode1, BranchNode2, BranchNode3, BranchNode4, BranchNode5, BranchNode6, BranchNode7, BranchNode8, BranchNode9, BranchNodeA, BranchNodeB, BranchNodeC, BranchNodeD, BranchNodeE and BranchNodeF. BranchNode's underlying storage implementation includes a HashKey(Hash of BranchNode's binary raw data, used to support state object verification based on light client protocol) and a StorageKey(UpdateNonce(A natural number starting from 0 and increments by 1 with each modification of the BranchNode) of BranchNode, used to access state objects from StateDB).

#### **2.10.1.2 About BranchNode Status**

BranchNode Status is used to identify the composition of the state objects included in the BranchNode. The type of the BranchNode Status state object is [EQCBits](#).

The default order of state objects that BranchNode includes is: BranchNode0, BranchNode1, BranchNode2, BranchNode3, BranchNode4, BranchNode5, BranchNode6, BranchNode7, BranchNode8, BranchNode9, BranchNodeA, BranchNodeB, BranchNodeC, BranchNodeD, BranchNodeE, BranchNodeF, and Value.

BranchNode Status consists of two status types at the current

stage(in the underlying storage, they are compositely stored together):

1. HashStatus, the default universal identifier bit of the BranchNode which participate in the calculation of the BranchNode Hash.

0<sup>44</sup> 0<sup>45</sup> 0<sup>46</sup> 0<sup>47</sup> 0<sup>48</sup> 0<sup>49</sup> 0<sup>50</sup> 0<sup>51</sup> 0<sup>52</sup> 0<sup>53</sup> 0<sup>54</sup> 0<sup>55</sup> 0<sup>56</sup> 0<sup>57</sup> 0<sup>58</sup> 0<sup>59</sup> 0<sup>60</sup> 0<sup>61</sup>

2. StorageStatus, includes HashStatus identifier bit and storage relvant identifier bit of the BranchNode which does not participate in the calculation of the BranchNode Hash but it is used to get BranchNode from StateDB.

---

<sup>44</sup> Indicates whether BranchNode includes BranchNodeF, 0: excludes, 1: includes.

<sup>45</sup> Indicates whether BranchNode includes BranchNodeE, 0: excludes, 1: includes.

<sup>46</sup> Indicates whether BranchNode includes BranchNodeD, 0: excludes, 1: includes.

<sup>47</sup> Indicates whether BranchNode includes BranchNodeC, 0: excludes, 1: includes.

<sup>48</sup> Indicates whether BranchNode includes BranchNodeB, 0: excludes, 1: includes.

<sup>49</sup> Indicates whether BranchNode includes BranchNodeA, 0: excludes, 1: includes.

<sup>50</sup> Indicates whether BranchNode includes BranchNode9, 0: excludes, 1: includes.

<sup>51</sup> Indicates whether BranchNode includes BranchNode8, 0: excludes, 1: includes.

<sup>52</sup> Indicates whether BranchNode includes BranchNode7, 0: excludes, 1: includes.

<sup>53</sup> Indicates whether BranchNode includes BranchNode6, 0: excludes, 1: includes.

<sup>54</sup> Indicates whether BranchNode includes BranchNode5, 0: excludes, 1: includes.

<sup>55</sup> Indicates whether BranchNode includes BranchNode4, 0: excludes, 1: includes.

<sup>56</sup> Indicates whether BranchNode includes BranchNode3, 0: excludes, 1: includes.

<sup>57</sup> Indicates whether BranchNode includes BranchNode2, 0: excludes, 1: includes.

<sup>58</sup> Indicates whether BranchNode includes BranchNode1, 0: excludes, 1: includes.

<sup>59</sup> Indicates whether BranchNode includes BranchNode0, 0: excludes, 1: includes.

<sup>60</sup> Indicates whether BranchNode's key is one character or multiple characters, 0: one, 1: multiple.

When the key contains only one character, there is no need to store it, and it can be obtained directly according to the corresponding status bit of its parent HashNode. When the key contains multiple characters, there is no need to store its first character because it can be obtained directly according to the corresponding status bit of its parent HashNode.

<sup>61</sup> Indicates whether BranchNode is a branch node or a leaf node, 0: branch, 1: leaf.

0<sup>62</sup> 0<sup>63</sup> 0xxx0<sup>64</sup> 0000xxx0000<sup>65</sup> 00000000000000000000

Note : If Value exists, the smaller absolute value of the difference between its StorageKey and the StorageKey of the largest or smallest BranchNode will be stored.

### 2.10.2.3 About LeafNode

LeafNode is the leaf node that constitutes the HexMerkleDynamicPatriciaTrie dictionary tree. LeafNode is used to store state objects. LeafNode has a status, a StateObjectMate or StateObjectMateArray<sup>66</sup> and its relevant governance state objects. LeafNode related governance state objects can be extended as needed through its status state object. A HashKey collisionless identifier<sup>67</sup> bit is included in the current status to identify whether the current

---

<sup>62</sup> If Value exists indicates the absolute value of the difference between Value's StorageKey and the StorageKey of the largest or smallest BranchNode which is smaller, 0: the smallest, 1: the largest.

<sup>63</sup> Identifies whether the value's StorageKey is larger or smaller, 0: smaller, 1: larger.

<sup>64</sup> The 4-bit identifier identifies the sequence number of each BranchNode included in the current node sorted from small to large(when the StorageKeys of two adjacent BranchNodes are equal, the one with the lowest default order is taken).

<sup>65</sup> The one-bit flag identifies whether each BranchNode( from the second BranchNode sorted in ascending order) is equal to the adjacent BranchNode that is smaller than it.

<sup>66</sup> When the current LeafNode contains only one state object, only one StateObjectMate object is included. When the current LeafNode includes more than two state objects, the current LeafNode includes a StateObjectMateArray (its array subscript 0 represents 2 array elements, array subscript 1 represents 3 array elements, and so on).

<sup>67</sup> HashKey collisionless identifier identifies whether the current LeafNode includes state objects that have collisions, 0: collisionless, 1: collision.

LeafNode includes multiple state objects with the same HashKey.

#### **2.10.2.3.1 About StateObjectMate**

StateObjectMate is used to store state object and its relevant state objects. StateObjectMate has a status, a specific state object and its relevant state objects. StateObjectMate related governance state objects can be extended as needed through its status state object.

#### **2.10.2.3.2 About StateObjectMateArray**

StateObjectMateArray is used to simultaneously store multiple StateObjectMates, which contain state objects with the same HashKey. These state objects can be identified and distinguished by their UUID(Universally Unique Identifier)s, which are generated by specific algorithms based on the type, raw data, and associated unique identifiers of specific state objects.

#### **2.10.2.3.3 The HashKey collisionless design of HexMerklePatriciaTrie**

Before accessing a specific state object in the

HexMerklePatriciaTrie, the global unique access lock bound to its HashKey must be obtained first, and the related state object can be read, written and deleted only after the access right of the access lock is obtained. After the access operation of the relevant state object is completed, its access lock needs to be released.

Read operation:

When performing a read operation, if the current HashKey does not exist, null is returned directly.

When performing a read operation, if the current LeafNode does not have a HashKey collision, it will directly return it including StateObjectMate, and then obtain the corresponding state object from the StateObjectMate according to the UUID provided by the current read operation.

When performing a read operation, if the current LeafNode has a HashKey collision, the StateObjectMateArray included in it will be returned, and then obtains the corresponding state object from the StateObjectMateArray according to the UUID provided by the current read operation.

Write operation:

When performing a write operation, if the current HashKey

does not exist, the current state object is directly stored in the corresponding LeafNode.

When performing a write operation, if the current HashKey exists, and if the current LeafNode does not have a HashKey collision, then compare whether the UUID of the state object contained in the StateObjectMate currently contained in it is consistent with the UUID of the state object to be stored? If the UUIDs are consistent, the corresponding storage is directly overwritten. Otherwise, if the UUIDs are inconsistent, this is a HashKey collision. In this case, the HashKey collisionless identifier of the current LeafNode will be marked as 1 and the StateObjectMateArray will be used to simultaneously store the two state objects.

When performing a write operation, if the current HashKey exists, and if the current LeafNode has a HashKey collision, then compare the UUID of the state object stored in the current StateObjectMateArray one by one with the UUID of the state object to be stored. If the UUID of a state object stored in the current StateObjectMateArray is consistent with the UUID of the state object to be stored, the corresponding state object is directly overwritten and stored. If the UUIDs of all the state objects stored in the current

StateObjectMateArray are inconsistent with the UUID of the state object to be stored, add a new StateObjectMate array element containing the state object currently to be stored in the StateObjectMateArray to store it.

Delete operation:

When performing a delete operation, if the current HashKey does not exist, do nothing.

When performing a delete operation, if the current HashKey exists, and if the current LeafNode does not have a HashKey collision, then compare whether the UUID of the state object contained in the StateObjectMate contained in it is consistent with the UUID provided by the current delete operation. If they are consistent, delete the current LeafNode, otherwise do nothing.

When performing a delete operation, if the current HashKey exists, and if the current LeafNode has a HashKey collision, then compare the UUID of the state object stored in the current StateObjectMateArray one by one with the UUID of the state object to be deleted. If the UUID of a state object stored in the current StateObjectMateArray is consistent with the UUID of the state object to be deleted, the corresponding

StateObjectMate is directly deleted(If the current StateObjectMateArray contains only one StateObjectMate after the delete operation, then mark the HashKey collisionless identifier of the current LeafNode as 0, and delete the current StateObjectMateArray then store the StateObjectMate it contains directly in the LeafNode), otherwise do nothing.

## **2.11 Trusted State Object Verification Protocol**

Trusted State Object Verification Protocol is used to prove that a specific state object has been verified by the full node based on the merkle patricia trie proof associated with it.

## **2.12 About EQcoinBlock**

EQcoinBlock has a EQcoinBlockHeader, and a body (the relevant transactions that are added to the EQcoin blockchain).

### **2.12.1 About SingularityBlock**

The SingularityBlock is the first block of EQcoin, and the No. 1 to No. 1001 Passports will be issued in this block. Due to "Without time at the moment," SingularityBlock timestamp is zero.

## **2.12.2 About EQcoinBlockHeader**

EQcoinBlockHeader has a ProtocolVersion, a Status, a ParentHash, a BlockNumber, a Timestamp, a TotalSupply, a TotalPassportNumbers, a TotalTransactionNumbers, a StateRoot, a TransactionRoot, a PowerUsed, a BeneficiaryPassportID, a Difficulty, and a Nonce.

### **2.12.3 EQcoinBlock included transactions sorting priority design**

EQcoinBlock first packages the transactions with a higher power price (sorted by power price from highest to lowest, and when the power prices are equal, sorted by Passport ID from smallest to largest) and then packages the transactions with the default power price (sorted by Passport ID from smallest to largest).

Each EQcoinBlock can only include one transaction for a specific Passport, thus maintaining a balance that increases the accounting probability of high-ID Passport transactions.

### **2.12.4 EQcoinBlock included transactions packaging design**

In order to quickly parse EQcoinBlock, the transactions it

contains will be divided into N (positive integer) EQcoinBlock pieces of approximately the same size.

The EQcoinBlock piece storage structure consists of two state objects: L(length) state object(the EQcoinBlock piece length, its data type is EQCBits, its count index does not start from 0 but from 69 (because the size of the smallest transaction is 69 bytes)) and V(value) state object(the EQcoinBlock piece body).

This feature is not supported in the Inception phase.

### **2.12.5 EQcoinBlock's block time interval and maximum TPS**

EQcoin's block time interval is about 15 second, and the TPS is approximately 1000.

### **2.12.6 EQcoinBlock included transactions concurrent execution design**

The transaction processing process included in EQcoinBlock consists of two stages: transaction verification stage and transaction execution stage.

### **2.12.6.1 Transaction verification stage**

The transaction verification phase will concurrently verify the validity of all transactions contained in the current block according to the EQcoin transaction verification specifications, such as verifying whether their ordering, signature, nonce, balance, etc. are valid.

### **2.12.6.2 Transaction execution stage**

The transaction execution phase will be executed concurrently in units of execution unit queues. The sub-transaction state objects contained in the transaction will be placed in the corresponding execution unit queue according to their types. Execution unit queues include Transfer&OP execution unit queues and SmartContract execution unit queues.

The Transfer&OP state objects of each transaction included in the Transfer&OP execution unit queue will be executed concurrently.

The SmartContract execution unit queue is divided into atomic SmartContract execution unit queue and composite SmartContract execution unit queue according to whether there is a coupling relationship between SmartContracts to

call each other's smart contract functions.

If a SmartContract does not have a smart contract function calling coupling relationship with any other SmartContract, then it is an atomic SmartContract execution unit queue, and the sub-SmartContract state objects of each transaction it contains will be executed in sequence according to the order in which the transactions are sorted.

If there is a coupling relationship between smart contract functions calling each other between multiple SmartContracts, then they will form a composite SmartContract execution unit queue as a whole, and the sub-SmartContract state objects of each transaction contained in it will be executed in sequence according to the order in which the transactions are sorted.

The Transfer&OP execution unit queue, each atomic SmartContract execution unit queue, and each composite SmartContract execution unit queue will execute concurrently.

## **2.13 About EQcoinFBI**

EQcoinFBI is an abbreviation for "EQcoin Federated Byzantine Intelligence". It is an intelligent federated Byzantine agreement. It is the consensus mechanism of EQcoin.

## **2.14 EQcoin roadmap**

Stage 1 - Inception

EQcoin mainnet online.

Stage 2 - Era

EQcoin supports Intelligent and EQCVM, decentralized exchange based on Matchmaking Transaction Protocol and Lightning Network (LN).

Stage 3 - New dawn

EQcoin supports cross chain through the Interchain Communication Protocol.

Stage 4 - Nirvana

EQcoin moves from PoW to PoS.

## **2.15 EQcoin milestones**

2018-01-01 EQcoin officially launched.

2018-04-10 GitHub Initial commit.

2019 Establish an EQcoin test network to achieve multiple miner nodes based on PoW consensus mechanisms to mine, send transactions(issue Passport, transfer EQC and change lock), verify blocks, and compete the longest blockchain.

2020-02-10 Register the domain name of [www.eqcoin.org](http://www.eqcoin.org).

2021-02-12 Create [EQcoin organization](#) in GitHub.

2021-04 Create [EQcoin twitter](#).

2021-04 Create [EQcoin facebook](#).

At present, the overall design of the Inception phase of EQcoin has been completed. We have written thousands of pages of research and development technology documents and the code is about 80% complete and including a total of 33000+ lines.

## **2.16 EQcoin GitHub**

<https://github.com/EQcoin>

## **2.17 EQcoin developer community**

Currently, we have 11 members and 8 outside collaborators. You can visit <https://github.com/orgs/EQcoin/people> to learn more about our developer community.

## **2.18 EQcoin Thanksgiving Day**

September 19th is EQcoin Thanksgiving Day.

To express gratitude for the contributions of Bitcoin's founder, Satoshi Nakamoto, a donation of 1,010,000 EQCs is being presented to him.

To express gratitude for the contributions of Ethereum's founders - Vitalik Buterin, Anthony Di Iorio, Charles Hoskinson, Mihai Alisie, Amir Chetrit, Joseph Lubin, Gavin Wood, and Jeffrey Wilcke - a donation of 80,000 EQCs is being presented to them.

To express gratitude for the contributions of the EQcoin developer community, a donation of 1,180,000 EQCs is being presented to them.
